Interpretations using logs

The most common transformation of either the response or explanatory variable(s) is to take logarithms because

- linearity will often then be approximately true,
- the variance will likely be approximately constant, and
- there is a (relatively) convenient interpretation.

We will talk about interpretation of β_0 and β_1 when

- only the response is logged,
- only the explanatory variable is logged, and
- when both are logged.

Neither response nor explanatory variable are logged

If

$$E[Y|X] = \beta_0 + \beta_1 X,$$

then

- β_0 is the expected response when X is zero and
- β_1 is the expected change in the response for a one unit increase in the explanatory variable.

For the following discussion,

- Y is always going to be the original response and
- X is always going to be the original explanatory variable.

Example

Suppose

- Y is corn yield per acre
- X is fertilizer level in lbs/acre

Then, if

$$E[Y|X] = \beta_0 + \beta_1 X$$

- β_0 is the expected corn yield per acre when fertilizer level is zero and
- β_1 is the expected change in corn yield per acre when fertilizer is increase by 1 lbs/acre.

Response is logged

Then, if

$$E[\log(Y)|X] = \beta_0 + \beta_1 X$$

then

$$\text{Median}[Y|X] = e^{\beta_0} e^{\beta_1 X}$$

then

- β_0 is the expected $\log(Y)$ when X is zero and
- β_1 is the expected change in $\log(Y)$ for a one unit increase in the explanatory variable.

Alternatively,

- e^{β_0} is the median of Y when X is zero and
- e^{β_1} is the multiplicative effect on the median of Y for a one unit increase in the explanatory variable.

since

$$\text{Median}[Y|X = x + 1] = e^{\beta_1} \text{Median}[Y|X = x + 1].$$

Response is logged

Suppose

- Y is corn yield per acre
- X is fertilizer level in lbs/acre

Then, if

$$E[\log(Y)|X] = \beta_0 + \beta_1 X$$

then

$$\text{Median}[Y|X] = e^{\beta_0} e^{\beta_1 X}$$

- e^{β_0} is the median corn yield per acre when fertilizer level is 0 and
- e^{β_1} is the multiplicative effect in median corn yield per acre when fertilizer is increased by 1 lbs/acre.

Explanatory variable is logged

If

$$E[Y|X] = \beta_0 + \beta_1 \log(X),$$

then

- β_0 is the expected response when $\log(X)$ is zero and
- β_1 is the expected change in the response for a one unit increase in $\log(X)$.

Alternatively,

- β_0 is the expected response when X is 1 and
- $\beta_1 \log(d)$ is the expected change in the response when X increase multiplicatively by d, e.g.
  - $\beta_1 \log(2)$ is the expected change in the response for each doubling of X or
  - $\beta_1 \log(10)$ is the expected change in the response for each ten-fold increase in X.

Explanatory variable is logged

Suppose

- Y is corn yield per acre
- X is fertilizer level in lbs/acre

Then, if

$$E[Y|X] = \beta_0 + \beta_1 \log(X)$$

- β_0 is the expected corn yield per acre when fertilizer level is 1 lb/acre and
- $\beta_1 \log(2)$ is the expected change in corn yield when fertilizer level is doubled.

Both response and explanatory variable are logged

If

$$E[\log(Y)|X] = \beta_0 + \beta_1 \log(X),$$

then

$$\text{Median}[Y|X] = e^{\beta_0} e^{\beta_1 \log(X)} = e^{\beta_0} X^{\beta_1},$$

and

- β_0 is the expected $\log(Y)$ when $\log(X)$ is zero and
- β_1 is the expected change in $\log(Y)$ for a one unit increase in $\log(X)$.

Alternatively,

- e^{β_0} is the median of Y when X is 1 and
- d^{β_1} is the multiplicative change in the median of the response when X increase multiplicatively by d, e.g.
  - 2^{β_1} is the multiplicative effect on the median of the response for each doubling of X or
  - 10^{β_1} is the multiplicative effect on the median of the response for each ten-fold increase in X.

Both response and explanatory variable are logged

Suppose

- Y is corn yield per acre
- X is fertilizer level in lbs/acre

Then, if

$$E[\log(Y)|X] = \beta_0 + \beta_1 \log(X) \quad \text{or} \quad \text{Median}[Y|X] = e^{\beta_0} e^{\beta_1 \log(X)} = e^{\beta_0} X^{\beta_1}$$

- e^{β_0} is the median corn yield per acre when fertilizer level is 1 lb/acre and
- 2^{β_1} is the multiplicative effect on median corn yield per acre when fertilizer level doubles.

Summary of interpretations when using logarithms

- When using the log of the response,
  - β_0 will affect the median response
  - β_1 will affect the multiplicative change in the median response
- When using the log of the explanatory variable (X),
  - β_0 will affect the response when $X = 1$
  - β_1 will affect the change in the response when there is a multiplicative change in X

To construct confidence intervals for e^{β}, find a confidence interval for β and exponentiate the endpoints, i.e. if (L, U) is a confidence interval for β, then (e^L, e^U) is a confidence interval for e^{β}.

Breakdown times

In an industrial laboratory, under uniform conditions, batches of electrical insulating fluid were subjected to constant voltages (kV) until the insulating property of the fluids broke down. Seven different voltage levels were studied and the measured reponses were the times (minutes) until breakdown.
