

Multiparameter models (cont.)

Dr. Jarad Niemi

STAT 544 - Iowa State University

February 14, 2019

Outline

- Multinomial
- Multivariate normal
 - Unknown mean
 - Unknown mean and covariance

In the process, we'll introduce the following distributions

- Multinomial
- Dirichlet
- Multivariate normal
- Inverse Wishart (and Wishart)
- normal-inverse Wishart distribution

Motivating examples

Multivariate count data:

- Item-response (Likert scale)

- Voting

Multinomial distribution

Suppose there are K categories and each individual independently chooses category k with probability π_k such that $\sum_{k=1}^K \pi_k = 1$. Let

- $Y_k \in \{0, 1, \dots, n\}$ be the number of individuals who choose category k
- with $n = \sum_{k=1}^K Y_k$ being the total number of individuals.

Then $Y = (Y_1, \dots, Y_K)$ has a multinomial distribution, i.e. $Y \sim Mult(n, \pi)$, with probability mass function (pmf)

$$p(y) = n! \prod_{k=1}^K \frac{\pi_k^{y_k}}{y_k!}.$$

Properties of the multinomial distribution

The multinomial distribution with pmf:

$$p(y) = n! \prod_{k=1}^k \frac{\pi_k^{y_k}}{y_k!}$$

has the following properties:

- $E[Y_k] = n\pi_k$
- $Var[Y_k] = n\pi_k(1 - \pi_k)$
- $Cov[Y_k, Y_{k'}] = -n\pi_k\pi_{k'}$ for $k \neq k'$

Marginally, each component of a multinomial distribution is a binomial distribution with $Y_k \sim Bin(n, \pi_k)$.

Dirichlet distribution

Let $\pi = (\pi_1, \dots, \pi_K)$ have a Dirichlet distribution, i.e. $\pi \sim \text{Dir}(a)$, with concentration parameter $a = (a_1, \dots, a_K)$ where $a_k > 0$ for all k .

The probability density function (pdf) for π is

$$p(\pi) = \frac{1}{\text{Beta}(a)} \prod_{k=1}^K \pi_k^{a_k-1}$$

with $\sum_{k=1}^K \pi_k = 1$ and $\text{Beta}(a)$ is the beta function, i.e.

$$\text{Beta}(a) = \frac{\prod_{k=1}^K \Gamma(a_k)}{\Gamma(\sum_{k=1}^K a_k)}.$$

Properties of the Dirichlet distribution

The Dirichlet distribution with pdf

$$p(\pi) \propto \prod_{k=1}^K \pi_k^{a_k-1}$$

has the following properties (where $a_0 = \sum_{k=1}^K a_k$):

- $E[\pi_k] = \frac{a_k}{a_0}$
- $Var[\pi_k] = \frac{a_k(a_0 - a_k)}{a_0^2(a_0 + 1)}$
- $CoVar[\pi_k, \pi_{k'}] = \frac{-a_k a_{k'}}{a_0^2(a_0 + 1)}$

Marginally, each component of a Dirichlet distribution is a beta distribution with $\pi_k \sim Be(a_k, a_0 - a_k)$.

Bayesian inference

The conjugate prior for a multinomial distribution, i.e. $Y \sim \text{Mult}(n, \pi)$, with unknown probability vector π is a Dirichlet distribution. The Jeffreys prior is a Dirichlet distribution with $a_k = 0.5$ for all k . Some argue that for large K , this prior will put too much mass on rare categories and would suggest the Dirichlet prior with $a_k = 1/K$ for all k .

The posterior under a Dirichlet prior is

$$\begin{aligned} p(\pi|y) &\propto p(y|\pi)p(\pi) \\ &\propto \left[\prod_{k=1}^K \pi_k^{y_k} \right] \left[\prod_{k=1}^K \pi_k^{a_k-1} \right] \\ &= \prod_{k=1}^K \pi_k^{a_k+y_k-1} \end{aligned}$$

Thus $\pi|y \sim \text{Dir}(a + y)$.

Multivariate normal distribution

Let $Y = (Y_1, \dots, Y_K) \in \mathbb{R}^K$ have a multivariate normal distribution, i.e. $Y \sim N_K(\mu, \Sigma)$ with mean μ and positive definite variance-covariance matrix Σ .

The probability density function (pdf) for Y is

$$p(y) = (2\pi)^{-k/2} |\Sigma|^{-1/2} \exp \left(-\frac{1}{2} (y - \mu)^\top \Sigma^{-1} (y - \mu) \right).$$

Bivariate normal contours

Contours of a bivariate normal with correlation of 0.8

Properties of the multivariate normal distribution

The multivariate normal distribution with pdf

$$p(y) = (2\pi)^{-k/2} |\Sigma|^{-1/2} \exp \left(-\frac{1}{2} (y - \mu)^\top \Sigma^{-1} (y - \mu) \right)$$

has the following properties:

- $E[Y_k] = \mu_k$
- $Var[Y_k] = \Sigma_{kk}$
- $CoVar[Y_k, Y_{k'}] = \Sigma_{k,k'}$
- Marginally, each component of a multivariate normal distribution is a normal distribution with $Y_k \sim N(\mu, \Sigma_{kk})$.
- Conditional distributions are also normal, i.e. if

$$\begin{pmatrix} Y_1 \\ Y_2 \end{pmatrix} \sim N \left(\begin{bmatrix} \mu_1 \\ \mu_2 \end{bmatrix}, \begin{bmatrix} \Sigma_{11} & \Sigma_{12} \\ \Sigma_{21} & \Sigma_{22} \end{bmatrix} \right)$$

then

$$Y_1 | Y_2 = y_2 \sim N \left(\mu_1 + \Sigma_{12} \Sigma_{22}^{-1} (y_2 - \mu_2), \Sigma_{11} - \Sigma_{12} \Sigma_{22}^{-1} \Sigma_{21} \right).$$

Representing independence in a multivariate normal

Let $Y \sim N(\mu, \Sigma)$ with precision matrix $\Omega = \Sigma^{-1}$.

- If $\Sigma_{k,k'} = 0$, then Y_k and $Y_{k'}$ are independent of each other.
- If $\Omega_{k,k'} = 0$, then Y_k and $Y_{k'}$ are conditionally independent of each other given Y_j for $j \neq k, k'$.

Default inference with an unknown mean

Let $Y_i \stackrel{\text{ind}}{\sim} N_K(\mu, S)$ with default prior $p(\mu) \propto 1$ where $Y_i = (Y_{i1}, \dots, Y_{iK})$, then

$$\begin{aligned} p(\mu|y) &\propto p(y|\mu)p(\mu) \\ &\propto \exp\left(-\frac{1}{2} \sum_{i=1}^n (y_i - \mu)^\top S^{-1} (y_i - \mu)\right) \\ &= \exp\left(-\frac{1}{2} \text{tr}(S^{-1} S_0)\right) \end{aligned}$$

where

$$S_0 = \sum_{i=1}^n (y_i - \mu)(y_i - \mu)^\top.$$

This posterior is proper if $n \geq K$ and, in that case, is

$$\mu|y \sim N_K\left(\bar{y}, \frac{1}{n}S\right).$$

where this $\bar{y} = (\bar{y}_1, \dots, \bar{y}_K)$ has elements

$$\bar{y}_k = \frac{1}{n} \sum_{i=1}^n \bar{y}_{ik}.$$

Conjugate inference with an unknown mean

Let $Y_i \stackrel{ind}{\sim} N(\mu, S)$ with conjugate prior $\mu \sim N_K(m, C)$

$$\begin{aligned} p(\mu|y) &\propto p(y|\mu)p(\mu) \\ &\propto \exp\left(-\frac{1}{2}\sum_{i=1}^n (y_i - \mu)^\top S^{-1}(y_i - \mu)\right) \\ &\quad \times \exp\left(-\frac{1}{2}(\mu - m)^\top C^{-1}(\mu - m)\right) \\ &= \exp\left(-\frac{1}{2}(\mu - m')^\top C'^{-1}(\mu - m')\right) \end{aligned}$$

and thus

$$\mu|y \sim N(m', C')$$

where

$$\begin{aligned} C' &= [C^{-1} + nS^{-1}]^{-1} \\ m' &= C' [C^{-1}m + nS^{-1}\bar{y}]. \end{aligned}$$

Inverse Wishart distribution

Let the $K \times K$ matrix Σ have an inverse Wishart distribution, i.e. $\Sigma \sim IW(v, W^{-1})$, with degrees of freedom $v > K - 1$ and positive definite scale matrix W .

The pdf for Σ is

$$p(\Sigma) \propto |\Sigma|^{-(v+K+1)/2} \exp \left(-\frac{1}{2} \text{tr} (W\Sigma^{-1}) \right).$$

Properties of the inverse Wishart distribution

The inverse Wishart distribution with pdf

$$p(\Sigma) \propto |\Sigma|^{-(v+K+1)/2} \exp\left(-\frac{1}{2}\text{tr}(W\Sigma^{-1})\right).$$

has the following properties:

- $E[\Sigma] = (v - K - 1)^{-1}W$ for $v > K + 1$.
- Marginally, $\sigma_k^2 = \Sigma_{kk} \sim \text{Inv} - \chi^2(v, W_{kk})$.
- If a $K \times K$ matrix W has a Wishart distribution, i.e. $W \sim \text{Wishart}(v, S)$, then $W^{-1} \sim \text{IW}(v, S^{-1})$.

Normal-inverse Wishart distribution

A multivariate generalization of the normal-scaled-inverse- χ^2 distribution is the normal-inverse Wishart distribution. For a vector $\mu \in \mathbb{R}^K$ and $K \times K$ matrix Σ , the normal-inverse Wishart distribution is

$$\begin{aligned}\mu|\Sigma &\sim N(m, \Sigma/c) \\ \Sigma &\sim IW(v, W^{-1})\end{aligned}$$

The marginal distribution for μ , i.e.

$$p(\mu) = \int p(\mu|\Sigma)p(\Sigma)d\Sigma,$$

is a multivariate t-distribution, i.e.

$$\mu \sim t_{v-K+1}(m, W/[c(v-K+1)]).$$

Conjugate inference with unknown mean and covariance

Let $Y_i \stackrel{\text{ind}}{\sim} N(\mu, \Sigma)$ with conjugate prior

$$\mu|\Sigma \sim N(m, \Sigma/c) \quad \Sigma \sim IW(v, W^{-1})$$

which has pdf

$$p(\mu, \Sigma) \propto |\Sigma|^{-((v+K)/2+1)} \exp \left(-\frac{1}{2} \text{tr}(W\Sigma^{-1}) - \frac{c}{2} (\mu - m)^\top \Sigma^{-1} (\mu - m) \right).$$

The posterior is a normal-inverse Wishart with parameters

$$\begin{aligned} c' &= c + n \\ v' &= v + n \\ m' &= \frac{k}{k+n} m + \frac{n}{k+n} \bar{y} \\ W' &= W + S + \frac{kn}{k+n} (\bar{y} - m)(\bar{y} - m)^\top \end{aligned}$$

where

$$S = \sum_{i=1}^n (y_i - \bar{y})(y_i - \bar{y})^\top.$$

Default inference with unknown mean and covariance

- The prior $\Sigma \sim IW(K + 1, I)$ is non-informative in the sense that marginally each correlation has a uniform distribution on $(-1, 1)$.
- The prior

$$p(\mu, \Sigma) \propto |\Sigma|^{-(K+1)/2},$$

which can be thought of as a normal-inverse-Wishart distribution with $c \rightarrow 0$, $v \rightarrow -1$, and $|W| \rightarrow 0$, results in the posterior distribution

$$\begin{aligned}\mu|\Sigma, y &\sim N(\bar{y}, \Sigma/n) \\ \Sigma|y &\sim IW(n - 1, S^{-1}).\end{aligned}$$

Issues with the inverse Wishart distribution

- Marginals of the IW have an IG (or scaled-inverse- χ^2) distribution and therefore inherit the low density near zero resulting in a (possible) bias for small variances toward larger values.
- Due to the above issue, and the relationship between the variances and the correlations (<http://www.themattsimpson.com/2012/08/20/prior-distributions-for-covariance-matrices-the-scaled-inverse-wishart-prior/>) the correlations can be biased:
 - small variances imply small correlations
 - large variances imply large correlations

Remedies:

- Don't blindly use I for the scale matrix in an IW, instead use a reasonable diagonal matrix for your data set.
- Use the scaled Inverse wishart distribution (see BDA3 pg 74)
- Use the separation strategy, i.e. $\Sigma = \Delta\Lambda\Delta$ where Δ is diagonal and Λ is a correlation matrix, where you specify the standard deviations (or variances) and correlations separately. In this case, Gelman recommends putting the LKJ prior (see page 582) on the correlation matrix.
