A Bayesian statistician

Let

- y be the data we will collect from an experiment,
- K be everything we know for certain about the world (aside from y), and
- θ be anything we don't know for certain.

My definition of a Bayesian statistician is an individual who makes decisions based on the probability distribution of those things we don't know conditional on what we know, i.e.

$$p(\theta|y, K).$$

Typically, the K is dropped from the notation.

Bayes' Rule

Bayes' Rule applied to a partition $P = \{A_1, A_2, \dots\}$,

$$P(A_i|B) = \frac{P(B|A_i)P(A_i)}{P(B)} = \frac{P(B|A_i)P(A_i)}{\sum_{i=1}^{\infty} P(B|A_i)P(A_i)}$$

Bayes' Rule also applies to probability density (or mass) functions, e.g.

$$p(\theta|y) = \frac{p(y|\theta)p(\theta)}{p(y)} = \frac{p(y|\theta)p(\theta)}{\int p(y|\theta)p(\theta)d\theta}$$

where the integral plays the role of the sum in the previous statement.

Parameter estimation

Let y be data from some model with unknown parameter θ . Then

$$p(\theta|y) = \frac{p(y|\theta)p(\theta)}{p(y)} = \frac{p(y|\theta)p(\theta)}{\int p(y|\theta)p(\theta)d\theta}$$

and we use the following terminology

Terminology	Notation
Posterior	$p(\theta y)$
Prior	$p(\theta)$
Model (likelihood)	$p(y \theta)$
Prior predictive distribution (marginal likelihood)	$p(y)$

If θ is discrete (continuous),

then $p(\theta)$ and $p(\theta|y)$ are probability mass (density) functions.

If y is discrete (continuous),

then $p(y|\theta)$ and $p(y)$ are probability mass (density) functions.

Binomial model

Suppose $Y \sim \text{Bin}(n, \theta)$, then

$$p(y|\theta) = \binom{n}{y} \theta^y (1 - \theta)^{n-y}.$$

A reasonable default prior is the uniform distribution on the interval $(0, 1)$

$$p(\theta) = \text{I}(0 < \theta < 1).$$

Using Bayes Rule, you can find

$$\theta|y \sim \text{Be}(1 + y, 1 + n - y).$$

Beta distribution

Definition

The **beta distribution** defines a distribution for a probability, i.e. a number on the interval $(0,1)$. The probability density function is

$$p(\theta) = \frac{\theta^{a-1}(1-\theta)^{b-1}}{Beta(a,b)} \mathbf{I}(0 < \theta < 1)$$

where $a, b > 0$ and $Beta$ is the beta function, i.e.

$$Beta(a,b) = \frac{\Gamma(a)\Gamma(b)}{\Gamma(a+b)} \quad \text{and} \quad \Gamma(a) = \int_0^\infty x^{a-1} e^{-x} dx.$$

The beta distribution has the following properties:

- $E[\theta] = \frac{a}{a+b}$
- $Var[\theta] = \frac{ab}{(a+b)^2(a+b+1)}.$

Beta posterior

Suppose we have made 100 sensors according to a particular protocol and 2 have a sensitivity below a pre-determined threshold. Let Y be the number below the threshold. Assume $Y \sim \text{Bin}(n, \theta)$ with $n = 100$ and $\theta \sim \text{Unif}(0, 1) \stackrel{d}{=} \text{Be}(1, 1)$, then

$$\theta|y \sim \text{Be}(1 + y, 1 + n - y) \stackrel{d}{=} \text{Be}(3, 99).$$

Posterior density

```
n <- 100
y <- 2
curve(dbeta(x, 1+y, 1+n-y), 0, 0.1,
      main = "Posterior density",
      xlab = expression(theta),
      ylab = expression(paste("p(", theta, "| y)")))
```

Posterior expectation

Often times it is inconvenient to provide a full posterior and so we often summarize using a point estimate from the posterior. For a point estimate, we can use the posterior expectation:

$$\hat{\theta}_{Bayes} = E[\theta|y] = \frac{1+y}{(1+y) + (1+n-y)} = \frac{1+y}{2+n}$$

```
(1+y)/(2+n)
```

```
[1] 0.02941176
```

Not that this is close, but not exactly equal to $\hat{\theta}_{MLE} = y/n$. Since the MLE is unbiased, this posterior expectation will generally be biased but it is still consistent since $\hat{\theta}_{Bayes} \rightarrow \hat{\theta}_{MLE}$.

Credible intervals

Definition

A $100(1 - \alpha)\%$ **credible interval** is any interval (L, U) such that

$$1 - \alpha = \int_L^U p(\theta|y)d\theta.$$

An **equal-tail** $100(1 - \alpha)\%$ **credible interval** is the interval L, U such that

$$\alpha/2 = \int_{-\infty}^L p(\theta|y)d\theta = \int_U^{\infty} p(\theta|y)d\theta.$$

```
# 95% credible interval is  
ci = qbeta(c(.025,.975), 1+y, 1+n-y)  
round(ci, 3)
```

```
[1] 0.006 0.070
```

Equal-tail 95% credible interval

Summary

Bayesian parameter estimation involves

1. Specifying a model $p(y|\theta)$ for your data.
2. Specifying a prior $p(\theta)$ for the parameter.
3. Deriving the posterior

$$p(\theta|y) = \frac{p(y|\theta)p(\theta)}{p(y)} \propto p(y|\theta)p(\theta).$$

4. Calculating quantities of interest, e.g.
 - Posterior expectation, $E[\theta|y]$
 - Credible interval

Bayesian analysis for binomial model summary

Let $Y \sim \text{Bin}(n, \theta)$ and assume $\theta \sim \text{Be}(a, b)$. Then

$$\theta|y \sim \text{Be}(a + y, b + n - y).$$

A default prior is $\theta \sim \text{Be}(1, 1) \stackrel{d}{=} \text{Unif}(0, 1)$.

R code for binomial analysis

```
a <- 1; b <- 1           # default uniform prior
y <- 3; n <- 10         # data

curve(dbeta(x, ay, b+n-y)) # posterior (pdf)
(a+y)/(a+b+n)             # posterior mean
qbeta(.5, a+y, b+n-y)     # posterior median
qbeta(c(.025, .975), a+y, b+n-y) # 95% equal tail credible interval

# Special cases
qbeta(.95, a+y, b+n-y)    # if y=0, use a lower one-sided credible interval (0 up to here)
qbeta(.05, a+y, b+n-y)    # if y=n, use a upper one-sided credible interval (here up to 1)
```
