

Student Name: _____

STAT 544 Mid-term Exam
Thursday 8 March 2018, 8:00-9:20

Instructor: Jarad Niemi

INSTRUCTIONS

Please check to make sure you have 4 pages with writing on the front and back (some pages are marked ‘intentionally left blank’). Feel free to remove the last page, i.e. the one with R code.

On the following pages you will find short answer questions related to the topics we covered in class for a total of 50 points. Please read the directions carefully.

You are allowed to use a calculator and one $8\frac{1}{2} \times 11$ sheet of paper with writing on both front and back. A non-exhaustive list of items you are not allowed to use are **cell phones, laptops, PDAs, and textbooks**. Cheating will not be tolerated. Anyone caught cheating will receive an automatic F on the exam. In addition the incident will be reported, and dealt with according to University’s Academic Dishonesty regulations. Please refrain from talking to your peers, exchanging papers, writing utensils or other objects, or walking around the room. All of these activities can be considered cheating. **If you have any questions, please raise your hand.**

You will be given only the time allotted for the course; no extra time will be given.

Good Luck!

1. In a location that rains only 5 days out of the year, a meteorologist has predicted rain for tomorrow. The meteorologist correctly predicts rain 95% of the time when it does rain and correctly predicts no rain 90% of the time when it does not rain. What is the probability it will rain tomorrow? (20 points)

2. A Pareto distribution for the random variable Y has a probability density function

$$p(y|\alpha, \beta) = \frac{\alpha\beta^\alpha}{y^{\alpha+1}}\mathbf{I}(\beta \leq y)$$

for shape $\alpha > 0$ and scale $\beta > 0$. For the following, assume you have observed y_1, \dots, y_n independent observations from the same Pareto distribution.

- (a) Suppose α is known and β is given a Pareto prior with shape a and scale b . Derive the posterior for β . (10 points)

- (b) Suppose β is known and $\alpha \sim Ga(a, b)$, i.e. $p(\alpha) \propto \alpha^{a-1}e^{-b\alpha}$. Derive the posterior for α . (10 points)

3. Assume the model $Y_i \stackrel{ind}{\sim} N(\mu, \sigma^2)$ $i = 1, \dots, n$ with prior where the probability density function is $p(y) = (2\pi\sigma^2)^{-1/2} \exp(-[y - \mu]^2/2\sigma^2)$. Assume the prior

$$p(\mu, \sigma^2) \propto \exp\left(-\frac{1}{2C}(\mu - m)^2\right) (\sigma^2)^{-a-1} e^{-b/\sigma^2}.$$

with $a > 0$, $b > 0$, and $C > 0$. Let $y = (y_1, \dots, y_n)$

- (a) Derive the conditional posterior for μ , i.e. $p(\mu|\sigma^2, y)$. (10 points)

- (b) Derive the conditional posterior for σ^2 , i.e. $p(\sigma^2|\mu, y)$. (10 points)

4. For the following questions, please refer to the pages titled R/Stan code and R/Stan output.

(a) Write down the model that is being fit including priors. (14 points)

(b) For **group 1**, provide estimates for the following quantities to 2 decimal places:

i. posterior expectation for the group mean (1 point)

ii. equal-tail 95% credible interval for the group mean (1 point)

iii. posterior expectation for the group standard deviation (2 points)

iv. equal-tail 95% credible interval for the group standard deviation (2 points)

5. Consider the hierarchical model

$$Y_{gi} \stackrel{ind}{\sim} Po(\lambda_g) \quad \text{and} \quad \lambda_g \stackrel{ind}{\sim} Ga(\alpha, \beta)$$

for groups $g = 1, \dots, G$ and individuals within a group $i = 1, \dots, n_i$. Assume some reasonable prior on α and β such that you can obtain posterior samples $\lambda_1^{(m)}, \dots, \lambda_G^{(m)}, \alpha^{(m)}, \beta^{(m)}$ from the joint posterior $p(\lambda_1, \dots, \lambda_G, \alpha, \beta | y)$ for $m = 1, \dots, M$.

- (a) The predictive distribution for a new, independent observation from group 1, \tilde{y}_1 , is

$$p(\tilde{y}_1 | y) = \int p(\tilde{y}_1 | \lambda_1) p(\lambda_1 | y) d\lambda_1.$$

Describe an algorithm to simulate values from this marginal distribution. (10 points)

- (b) State an integral equation (like that in the previous question) that would allow you to find the predictive distribution for a new observation from a new group, \tilde{y}_* . (10 points)

R/Stan code

```
d %>% group_by(group) %>% summarize(n=n(), mean=mean(y), sd=sd(y))
## # A tibble: 10 x 4
##   group      n    mean    sd
