Gibbs sampling

Dr. Jarad Niemi

Iowa State University

March 28, 2016

Outline

- Two-component Gibbs sampler
  - Full conditional distribution
- K-component Gibbs sampler
  - Blocked Gibbs sampler
- Metropolis-within-Gibbs
- Slice sampler
  - Latent variable augmentation

Gibbs sampling

Suppose our target distribution is $p(\theta|y)$ with $\theta = (\theta_1, \theta_2)$ and we can sample from $p(\theta_1|\theta_2, y)$ and $p(\theta_2|\theta_1, y)$. Beginning with an initial value (θ_1^0, θ_2^0), the Gibbs sampler is

    1. sample $\theta_1^t \sim p(\theta_1|\theta_2^{t-1}, y)$ and then

    2. sample $\theta_2^t \sim p(\theta_2|\theta_1^t, y)$.

Thus in order to run a Gibbs sampler, we need to derive the full conditional for θ_1 and θ_2, i.e. the distribution for θ_1 and θ_2 conditional on everything else.

Bivariate normal example

Let our target be

$$\theta \sim N_2(0, \Sigma) \qquad \Sigma = \left[\begin{array}{cc} 1 & \rho \\ \rho & 1 \end{array} \right].$$

Then

$$\begin{array}{rl} \theta_1 | \theta_2 & \sim N\left(\rho\theta_2, [1 - \rho^2]\right) \\ \theta_2 | \theta_1 & \sim N\left(\rho\theta_1, [1 - \rho^2]\right) \end{array}$$

are the conditional distributions.

Assuming initial value $\left(\theta_1^0, \theta_2^0\right)$, the Gibbs sampler proceeds as follows:

Iteration	Sample θ_1	Sample θ_2
1	$\theta_1^1 \sim N\left(\rho\theta_2^0, [1 - \rho^2]\right)$	$\theta_2^1 \sim N\left(\rho\theta_1^1, [1 - \rho^2]\right)$
	$\vdots$	
t	$\theta_1^t \sim N\left(\rho\theta_2^{t-1}, [1 - \rho^2]\right)$	$\theta_2^t \sim N\left(\rho\theta_1^t, [1 - \rho^2]\right)$
	$\vdots$	

R code for bivariate normal Gibbs sampler

```
gibbs_bivariate_normal = function(x0, n_points, rho) {
  x = matrix(x0, nrow=n_points, ncol=2, byrow=TRUE)
  v = sqrt(1-rho^2)
  for (i in 2:n_points) {
    x[i,1] = rnorm(1, rho*x[i-1,2], v)
    x[i,2] = rnorm(1, rho*x[i  ,1], v)
  }
  return(x)
}

x = gibbs_bivariate_normal(c(-3,3), n<-20, rho=rho<-0.9)
```

Normal model

Suppose $Y_i \stackrel{ind}{\sim} N(\mu, \sigma^2)$ and we assume the prior

$$\mu \sim N(m, C) \qquad \text{and} \qquad \sigma^2 \sim \text{Inv-}\chi^2(v, s^2).$$

Note: this is NOT the conjugate prior.

The full posterior we are interested in is

$$p(\mu, \sigma^2 | y) \propto \quad (\sigma^2)^{-n/2} \exp\left(-\frac{1}{2\sigma^2}(\sum_{i=1}^{n}(y_i - \mu)^2)\right) \exp\left(-\frac{1}{2C}(\mu - m)^2\right)$$
$$\times (\sigma^2)^{-(v/2+1)} \exp\left(-\frac{vs^2}{2\sigma^2}\right)$$

To run the Gibbs sampler, we need to derive

- $\mu | \sigma^2, y$ and
- $\sigma^2 | \mu, y$

Derive $\mu|\sigma^2, y$.

Recall

$$
\begin{aligned}
p(\mu, \sigma^2|y) \propto \; & (\sigma^2)^{-n/2} \exp\left(-\frac{1}{2\sigma^2}\sum_{i=1}^n (y_i - \mu)^2\right) \exp\left(-\frac{1}{2C}(\mu - m)^2\right) \\
& \times (\sigma^2)^{-(v/2+1)} \exp\left(-\frac{vs^2}{2\sigma^2}\right)
\end{aligned}
$$

Now find $\mu|\sigma^2, y$:

$$
\begin{aligned}
p(\mu|\sigma^2, y) \; & \propto p(\mu, \sigma^2|y) \\
& \propto \exp\left(-\frac{1}{2\sigma^2}\sum_{i=1}^n (y_i - \mu)^2\right) \exp\left(-\frac{1}{2C}(\mu - m)^2\right) \\
& \propto \exp\left(-\frac{1}{2}\left[\left(\frac{1}{\sigma^2/n} + \frac{1}{C}\right)\mu^2 - 2\mu\left(\frac{\bar{y}}{\sigma^2/n} + \frac{m}{C}\right)\right]\right)
\end{aligned}
$$

thus $\mu|\sigma^2, y \sim N(m', C')$ where

$$
\begin{aligned}
m' & = C'\left(\frac{\bar{y}}{\sigma^2/n} + \frac{m}{C}\right) \\
C' & = \left(\frac{1}{\sigma^2/n} + \frac{1}{C}\right)^{-1}
\end{aligned}
$$

Derive $\sigma^2|\mu, y$.

Recall

$$
\begin{aligned}
p(\mu, \sigma^2|y) \propto\ & (\sigma^2)^{-n/2} \exp\left(-\tfrac{1}{2\sigma^2}\sum_{i=1}^{n}(y_i - \mu)^2\right) \exp\left(-\tfrac{1}{2C}(\mu - m)^2\right) \\
& \times (\sigma^2)^{-(v/2+1)} \exp\left(-\tfrac{vs^2}{2\sigma^2}\right)
\end{aligned}
$$

Now find $\sigma^2|\mu, y$:

$$
\begin{aligned}
p(\sigma^2|\mu, y) \ &\propto p(\mu, \sigma^2|y) \\
&\propto (\sigma^2)^{-([v+n]/2+1)} \exp\left(-\tfrac{1}{2\sigma^2}\left[vs^2 + \sum_{i=1}^{n}(y_i - \mu)^2\right]\right)
\end{aligned}
$$

and thus $\sigma^2|\mu, y \sim \text{Inv-}\chi^2(v', (s')^2)$ where

$$
\begin{aligned}
v' &= v + n \\
v'(s')^2 &= vs^2 + \sum_{i=1}^{n}(y_i - \mu)^2
\end{aligned}
$$

R code for Gibbs sampler

```
# Data and prior
y = rnorm(10)
m = 0; C = 10
v = 1; s = 1

# Initial values
mu = 0
sigma2 = 1

# Save structures
n_iter = 1000
mu_keep = rep(NA, n_iter)
sigma_keep = rep(NA, n_iter)

# Pre-calculate
n = length(y)
sum_y = sum(y)
vp = v+n
vs2 = v*s^2
```
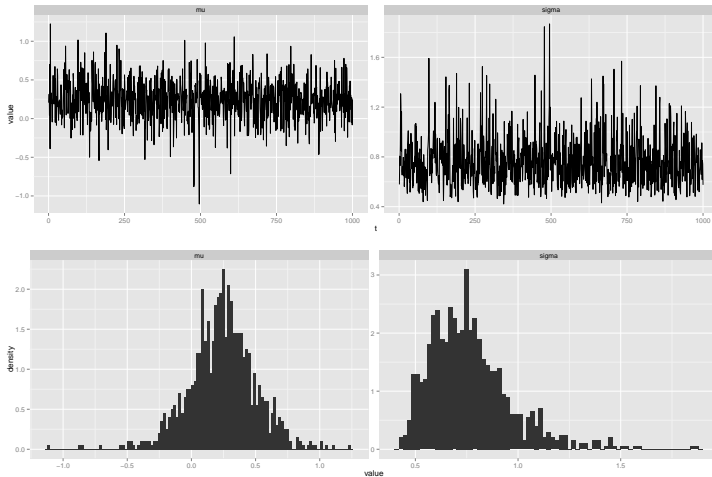

R code for Gibbs sampler

```
# Gibbs sampler
for (i in 1:n_iter) {
  # Sample mu
  Cp = 1/(n/sigma2+1/C)
  mp = Cp*(sum_y/sigma2+m/C)
  mu = rnorm(1, mp, sqrt(Cp))

  # Sample sigma
  vpsp2 = vs2 + sum((y-mu)^2)
  sigma2 = 1/rgamma(1, vp/2, vpsp2/2)

  # Save iterations
  mu_keep[i] = mu
  sigma_keep[i] = sqrt(sigma2)
}
```

Posteriors

K-component Gibbs sampler

Suppose $\theta = (\theta_1, \ldots, \theta_K)$, then the following Gibbs sampler can be constructed

$$
\begin{aligned}
\theta_1^t &\sim p\left(\theta_1 | \theta_2^{t-1}, \ldots, \theta_K^{t-1}, y\right) \\
\theta_2^t &\sim p\left(\theta_2 | \theta_1^t, \theta_3^{t-1}, \ldots, \theta_K^{t-1}, y\right) \\
&\vdots \\
\theta_k^t &\sim p\left(\theta_k | \theta_1^t \ldots, \theta_{k-1}^t, \theta_{k+1}^{t-1}, \ldots, \theta_K^{t-1}, y\right) \\
&\vdots \\
\theta_K^t &\sim p\left(\theta_K | \theta_1^t, \ldots, \theta_{K-1}^t, y\right)
\end{aligned}
$$

The distributions above are called the full conditional distributions. If some of the θ_k are vectors, then this is called a block Gibbs sampler.

Hierarchical normal model

Let
$$Y_{ij} \stackrel{ind}{\sim} N(\mu_i, \sigma^2), \qquad \mu_i \stackrel{ind}{\sim} N(\eta, \tau^2)$$
for $i = 1, \ldots, I$, $j = 1, \ldots, n_i$, $n = \sum_{i=1}^{I} n_i$ and prior
$$p(\eta, \tau^2, \sigma) \propto IG(\tau^2; a_\tau, b_\tau) IG(\sigma^2; a_\sigma, b_\sigma).$$

The full conditionals are
$$
\begin{aligned}
p(\mu|\eta, \sigma^2, \tau^2, y) &= \prod_{i=1}^{n} p(\mu_i|\eta, \sigma^2, \tau^2, y_i) \\
p(\mu_i|\eta, \sigma^2, \tau^2, y_i) &= N\left(\left[\frac{1}{\sigma^2/n_i} + \frac{1}{\tau^2}\right]\left[\frac{\overline{y}_i}{\sigma^2/n_i} + \frac{\eta}{\tau^2}\right], \left[\frac{1}{\sigma^2/n_i} + \frac{1}{\tau^2}\right]^{-1}\right) \\
p(\eta|\mu, \sigma^2, \tau^2, y) &= N\left(\overline{\mu}, \tau^2/I\right) \\
p(\sigma^2|\mu, \eta, \tau^2, y) &= IG(a_\sigma + n/2, b_\sigma + \sum_{i=1}^{I}\sum_{j=1}^{n_j}(y_{ij} - \mu_i)^2/2) \\
p(\tau^2|\mu, \eta, \sigma^2, y) &= IG(a_\tau + I/2, b_\tau + \sum_{i=1}^{I}(\mu_i - \eta)^2/2)
\end{aligned}
$$
where $n_i\overline{y}_i = \sum_{j=1}^{n_i} y_{ij}$ and $I\overline{\mu} = \sum_{i=1}^{I}\mu_i$.

Metropolis-within-Gibbs

We have discussed two Markov chain approaches to sample from a target distribution:

- Metropolis-Hastings algorithm
- Gibbs sampling

Gibbs sampling assumed we can sample from $p(\theta_k|\theta_{-k}, y)$ for all k, but what if we cannot sample from all of these full conditional distributions? For those $p(\theta_k|\theta_{-k})$ that cannot be sampled directly, a single iteration of the Metropolis-Hastings algorithm can be substituted.

Bivariate normal with $\rho = 0.9$

Reconsider the bivariate normal example substituting a Metropolis step in place of a Gibbs step:

```r
gibbs_and_metropolis = function(x0, n_points, rho) {
  x = matrix(x0, nrow=n_points, ncol=2, byrow=TRUE)
  v = sqrt(1-rho^2)
  for (i in 2:n_points) {
    x[i,1] = rnorm(1, rho*x[i-1,2], v)

    # Now do a random-walk Metropolis step
    x_prop = rnorm(1, x[i-1,2], 2.4*v) # optimal proposal variance
    logr   = dnorm(x_prop,    rho*x[i,1], v, log=TRUE) -
             dnorm(x[i-1,2], rho*x[i,1], v, log=TRUE)
    x[i,2] = ifelse(log(runif(1))<logr, x_prop, x[i-1,2])
  }
  return(x)
}

x = gibbs_and_metropolis(c(-3,3), n, rho)
length(unique(x[,2]))/length(x[,2]) # acceptance rate

[1] 0.5
```

Hierarchical normal model

Let

$$Y_{ij} \stackrel{ind}{\sim} N(\mu_i, \sigma^2), \qquad \mu_i \stackrel{ind}{\sim} N(\eta, \tau^2)$$

for $i = 1, \ldots, I$, $j = 1, \ldots, n_i$, $n = \sum_{i=1}^{I} n_i$ and prior

$$p(\eta, \tau^2, \sigma) \propto Ca^+(\tau^2; 0, b_\tau) Ca^+(\sigma^2; 0, b_\sigma).$$

The full conditionals are exactly the same except

$$
\begin{aligned}
p(\sigma^2 | \mu, \eta, \tau^2, y) & \propto IG(n/2, \textstyle\sum_{i=1}^{I} \sum_{j=1}^{n_j} (y_{ij} - \mu_i)^2/2) Ca^+(0, b_\sigma) \\
p(\tau^2 | \mu, \eta, \sigma^2, y) & \propto IG(I/2, \textstyle\sum_{i=1}^{I} (\mu_i - \eta)^2/2) Ca^+(0, b_\tau)
\end{aligned}
$$

where $n_i \overline{y}_i = \sum_{j=1}^{n_i} y_{ij}$ and $I \overline{\mu} = \sum_{i=1}^{I} \mu_i$.

Hierarchical normal model

To sample from $p(\theta|y) \propto IG(a, b)Ca^+(0, b_\theta)$, we have a variety of possibilities. Here are three:

1. Rejection sampling with $\theta^* \sim IG(a, b)$ and thus $M^*_{opt} = Ca^+(0; 0, b_\theta)$ and the acceptance probability is $Ca^+(\theta^*; 0, b_\theta)/M^*_{opt}$.

2. Independence Metropolis-Hastings with $\theta^* \sim IG(a, b)$ and thus the acceptance probability is $Ca^+(\theta^*; 0, b_\theta)/Ca^+(\theta^t; 0, b_\theta)$.

3. Random-walk Metropolis-Hastings with $\theta^* \sim g(\cdot|\theta^t)$ and acceptance probability is $q(\theta^*|y)/q(\theta^t|y)$.

Hierarchical binomial model

Let

$$
\begin{aligned}
Y_i &\overset{ind}{\sim} Bin(n_i, \theta_i) \\
\theta_i &\overset{iid}{\sim} Be(\alpha, \beta) \\
p(\alpha, \beta) &\propto (\alpha + \beta)^{-5/2}
\end{aligned}
$$

We will use a Gibbs sampler to sample from $\theta_1, \ldots, \theta_n, \alpha, \beta$, so we need to derive the following conditional distributions:

- $\theta_i | \theta_1, \ldots, \theta_{i-1}, \theta_{i+1}, \ldots, \theta_n, \alpha, \beta, y$
- $\alpha | \theta_1, \ldots, \theta_n, \beta, y$
- $\beta | \theta_1, \ldots, \theta_n, \alpha, y$

For shorthand, we often use $\theta_i | \ldots$ where $\ldots$ indicates *everything else*.

Full conditional for θ_i

$$Y_i \stackrel{ind}{\sim} Bin(n_i, \theta_i), \quad \theta_i \stackrel{iid}{\sim} Be(\alpha, \beta), \quad p(\alpha, \beta) \propto (\alpha + \beta)^{-5/2}$$

The full conditional for θ_i is

$$
\begin{aligned}
p(\theta_i | \ldots) & \propto p(y|\theta)p(\theta|\alpha, \beta)p(\alpha, \beta) \\
& \propto \left[\prod_{i=1}^{n} p(y_i|\theta_i)\right] \left[\prod_{i=1}^{n} p(\theta_i|\alpha, \beta)\right] \\
& \propto \prod_{j=1}^{n} \theta_j^{y_j}(1 - \theta_j)^{n_j - y_j}\theta_j^{\alpha-1}(1 - \theta_j)^{\beta-1} \\
& \propto \theta_i^{\alpha + y_i - 1}(1 - \theta_i)^{\beta + n_i - y_i - 1}
\end{aligned}
$$

Thus $\theta_i | \ldots \sim Be(\alpha + y_i, \beta + n_i - y_i)$.

Full conditional for α and β

$$Y_i \stackrel{ind}{\sim} Bin(n_i, \theta_i), \quad \theta_i \stackrel{iid}{\sim} Be(\alpha, \beta), \quad p(\alpha, \beta) \propto (\alpha + \beta)^{-5/2}$$

The full conditional for α is

$$
\begin{aligned}
p(\alpha | \ldots) &\propto p(y|\theta)p(\theta|\alpha, \beta)p(\alpha, \beta) \\
&\propto \left[\prod_{i=1}^n p(\theta_i|\alpha, \beta)\right] p(\alpha, \beta) \\
&\propto \frac{\left(\prod_{i=1}^n \theta_i\right)^{\alpha-1}}{Beta(\alpha, \beta)^n} (\alpha + \beta)^{-5/2}
\end{aligned}
$$

which is not a known density.

The full conditional for β is

$$
\begin{aligned}
p(\beta | \ldots) &\propto p(y|\theta)p(\theta|\alpha, \beta)p(\alpha, \beta) \\
&\propto \left[\prod_{i=1}^n p(\theta_i|\alpha, \beta)\right] p(\alpha, \beta) \\
&\propto \frac{\left(\prod_{i=1}^n [1-\theta_i]\right)^{\beta-1}}{Beta(\alpha, \beta)^n} (\alpha + \beta)^{-5/2}
\end{aligned}
$$

which is not a known density.

Full conditional functions

$$\log p(\alpha | \ldots) \propto (\alpha - 1) \sum_{i=1}^{n} \log (\quad \theta_i) + n \log(Beta(\alpha, \beta)) - 5/2 \log(\alpha + \beta)$$
$$\log p(\beta | \ldots) \propto (\beta - 1) \sum_{i=1}^{n} \log (1 - \theta_i) + n \log(Beta(\alpha, \beta)) - 5/2 \log(\alpha + \beta)$$

```
log_fc_alpha = function(theta, alpha, beta) {
  if (alpha<0) return(-Inf)
  n = length(theta)
  (alpha-1)*sum(log(theta))-n*lbeta(alpha,beta)-5/2*(alpha+beta)
}

log_fc_beta = function(theta, alpha, beta) {
  if (beta<0) return(-Inf)
  n = length(theta)
  (beta-1)*sum(log(1-theta))-n*lbeta(alpha,beta)-5/2*(alpha+beta)
}
```

```r
mcmc = function(n_sims, dat, inits, tune) {
  n_groups = nrow(dat)
  alpha = inits$alpha
  beta  = inits$beta

  # Recording structure
  theta_keep = matrix(NA, nrow=n_sims, ncol=n_groups)
  alpha_keep = rep(alpha, n_sims)
  beta_keep  = rep(beta , n_sims)

  for (i in 1:n_sims) {
    # Sample thetas
    theta = with(dat, rbeta(length(y), alpha+y, beta+n-y))

    # Sample alpha
    alpha_prop = rnorm(1, alpha, tune$alpha)
    logr = log_fc_alpha(theta, alpha_prop, beta)-log_fc_alpha(theta, alpha, beta)
    alpha = ifelse(log(runif(1))<logr, alpha_prop, alpha)

    # Sample beta
    beta_prop = rnorm(1, beta, tune$beta)
    logr = log_fc_beta(theta, alpha, beta_prop)-log_fc_beta(theta, alpha, beta)
    beta = ifelse(log(runif(1))<logr, beta_prop, beta)

    # Record parameter values
    theta_keep[i,] = theta
    alpha_keep[i]  = alpha
    beta_keep[ i]  = beta
  }

  return(data.frame(iteration=1:n_sims,
                    parameter=rep(c("alpha","beta",paste("theta[",1:n_groups,"]",sep="")),each=n_sims),
                    value=c(alpha_keep,beta_keep,as.numeric(theta_keep))))
}
```

Block Gibbs sampler

It appears that the Gibbs sampler we have constructed iteratively samples from

1. $\theta_1 \sim p(\theta_1|\theta_{-1}, \alpha, \beta, y)$

2. $\vdots$

3. $\theta_n \sim p(\theta_n|\theta_{-n}, \alpha, \beta, y)$

4. $\alpha \sim p(\alpha|\theta, \beta, y)$

5. $\beta \sim p(\beta|\theta, \alpha, y)$

where $\theta = (\theta_1, \ldots, \theta_n)$ and θ_{-i} is θ without element i.

But notice that

$$p(\theta|\alpha, \beta, y) = \prod_{i=1}^{n} p(\theta_i|\alpha, \beta, y_i)$$

and thus the θ_i are conditionally independent. Thus, we actually ran the following block Gibbs sampler:

1. $\theta \sim p(\theta|\alpha, \beta, y)$
2. $\alpha \sim p(\alpha|\theta, \beta, y)$
3. $\beta \sim p(\beta|\theta, \alpha, y)$

Slice sampling

Suppose the target distribution is $p(\theta|y)$ with scalar θ. Then,

$$p(\theta|y) = \int_0^{p(\theta|y)} du$$

Thus, $p(\theta|y)$ can be thought of as the marginal distribution of

$$(\theta, U) \sim \text{Unif}\{(\theta, u) : 0 < u < p(\theta|y)\}$$

where u is an auxiliary variable.

Slice sampling performs the following Gibbs sampler:

1. $u^t|\theta^{t-1}, y \sim \text{Unif}\{u : 0 < u < p(\theta^{t-1}|y)\}$ and
2. $\theta^t|u^t, y \sim \text{Unif}\{\theta : u^t < p(\theta|y)\}$.

Slice sampler for exponential distribution

Consider the target $\theta|y \sim Exp(1)$, then

$$\{\theta : u < p(\theta|y)\} = (0, -\log(u)).$$

Target disribution

Slice sampling in R

```
# Slice sampler
slice = function(n,init_theta,target,A) {
  u = theta = rep(NA,n)
  theta[1] = init_theta
  u[1] = runif(1,0,target(theta[1])) # This never actually gets used

  for (i in 2:n) {
    u[i] = runif(1,0,target(theta[i-1]))
    endpoints = A(u[i],theta[i-1]) # The second argument is used in the second example
    theta[i] = runif(1, endpoints[1],endpoints[2])
  }
  return(list(theta=theta,u=u))
}
# Exponential example
set.seed(6)
A = function(u,theta=NA) c(0,-log(u))
res = slice(10, 0.1, dexp, A)
```

Slice sampling approximation to Exp(1) distribution
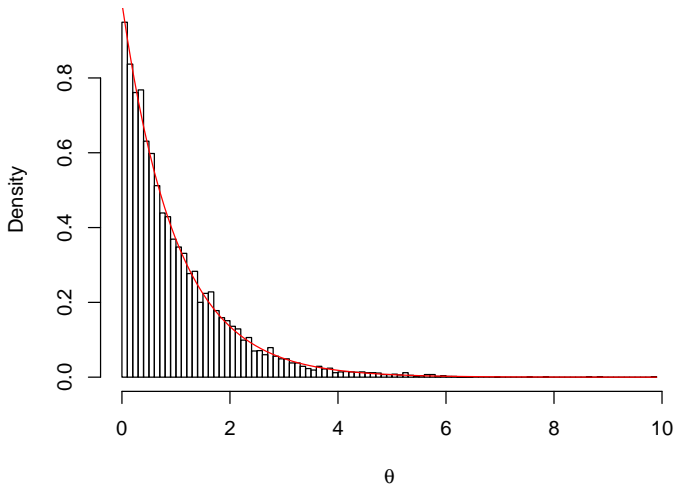

Summary

- Gibbs sampling breaks down a hard problem of sampling from a high dimensional distribution to a set of easier problems, i.e. sampling from low dimensional full conditional distributions.
- If the low dimensional distributions have an unknown form, then alternative methods can be used, e.g. (adaptive) rejection sampling, Metropolis-Hastings, etc.
- A Gibbs sampler can always be constructed by introducing an auxiliary variable that horizontally slices the target density.
