## One-way ANOVA (contrasts and multiple comparisons)

Jarad Niemi (Dr. J)

Iowa State University

last updated: October 13, 2014

Mice lifetimes

Simple hypothesis

Consider the one-way ANOVA model: $Y_{ij} \sim N(\mu_j, \sigma^2)$ where $j = 1, \ldots, J$.

Here are a few simple alternative hypotheses:

1. Mean lifetimes for N/R50 and R/R50 diet are different.
2. Mean lifetimes for N/R40 is different than for N/R50 and R/R50 combined.
3. Mean lifetimes for high calorie (NP and N/N85) diets is different than for low calorie diets combined.

$H_0 : \gamma = 0 \qquad H_1 : \gamma \neq 0 :$

$$
\begin{aligned}
\gamma_1 &= \mu_{R/R50} - \mu_{N/R50} \\
\gamma_2 &= \mu_{N/R40} - \tfrac{1}{2}(\mu_{N/R50} + \mu_{R/R50}) \\
\gamma_3 &= \tfrac{1}{4}(\mu_{N/R50} + \mu_{R/R50} + \mu_{N/R40} + \mu_{lopro}) - \tfrac{1}{2}(\mu_{NP} + \mu_{N/N85})
\end{aligned}
$$

Contrasts

Definition

A linear combination of group means has the form

$$\gamma = C_1 \mu_1 + C_2 \mu_2 + \ldots + C_J \mu_J$$

where C_j are known coefficients and μ_j are the unknown population means.

Definition

A linear combination with $C_1 + C_2 + \cdots + C_J = 0$ is a contrast.

Remark Contrast interpretation is usually best if
$|C_1| + |C_2| + \cdots + |C_J| = 2$, i.e. the positive sum to 1 and the negative coefficients sum to -1.

Inference on contrasts

$$\gamma = C_1\mu_1 + C_2\mu_2 + \cdots + C_J\mu_J$$

Estimated by

$$g = C_1\overline{Y}_1 + C_2\overline{Y}_2 + \cdots + C_J\overline{Y}_J$$

with standard error

$$SE(g) = s_p\sqrt{\frac{C_1^2}{n_1} + \frac{C_2^2}{n_2} + \cdots + \frac{C_J^2}{n_J}}$$

t-statistic (compare to t_{n-J}) and CI:

$$t = \frac{g}{SE(g)} \qquad g \pm t_{n-J}(1 - \alpha/2)SE(g)$$

Contrasts for mice lifetime dataset

For these contrasts:

1. Mean lifetimes for N/R50 and R/R50 diet are different.
2. Mean lifetimes for N/R40 is different than for N/R50 and R/R50 combined.
3. Mean lifetimes for high calorie (NP and N/N85) diets is different than for low calorie diets combined.

$H_0 : \gamma = 0 \qquad H_1 : \gamma \neq 0 :$

$$
\begin{aligned}
\gamma_1 &= \mu_{R/R50} - \mu_{N/R50} \\
\gamma_2 &= \mu_{N/R40} - \frac{1}{2}(\mu_{N/R50} + \mu_{R/R50}) \\
\gamma_3 &= \frac{1}{4}(\mu_{N/R50} + \mu_{R/R50} + \mu_{N/R40} + \mu_{lopro}) - \frac{1}{2}(\mu_{NP} + \mu_{N/N85})
\end{aligned}

NOTE: To ensure overall protection level, only probabilities associated with pre-planned
      comparisons should be used.

Statistical testing errors

Definition
A type I error occurs when a true null hypothesis is rejected.

Definition
A type II error occurs when a false null hypothesis is not rejected. Power is one minus the type II error probability.

Remark We set α to control the type I error probability. If we set $\alpha = 0.05$, then we will incorrectly reject a true null hypothesis 5% of the time.

Definition
The familywise error rate is the probability of rejecting at least one true null hypothesis.

Type I error for all pairwise comparisons of J groups

How many combinations when choosing 2 items out of J?

$$\binom{J}{2} = \frac{J!}{2!(J-2)!}.$$

If $J = 6$, then there are 15 different comparison of means. If we set $\alpha = 0.05$ as our significance level, then individually each test will only incorrectly reject 5% of the time.

If we have 15 tests and use $\alpha = 0.05$, what is the familywise error rate?

$$1 - (1 - 0.05)^{15} = 1 - (0.95)^{15} = 1 - 0.46 = 0.54$$

So there is a greater than 50% probability of falsely rejecting a true null hypothesis!
Bonferroni correction

Definition

If we do m tests and want the familywise error rate to be α, the Bonferroni correction uses α/m for each individual test. The familywise error rate, for independent tests, is $1 - (1 - \alpha/, m)^m$.

Bonferroni familywise error rate

SAS code and output for pairwise comparisons

Compare the unadjusted pvalues to $\alpha/15 = 0.05/15 = 0.0033$.

```
                    Least Squares Means for effect diet
                    Pr > |t| for H0: LSMean(i)=LSMean(j)

                    Dependent Variable: lifetime

  i/j        1          2          3          4          5          6

   1                  <.0001     <.0001     <.0001     <.0001     <.0001
   2     <.0001                  0.0166     <.0001     0.0731     <.0001
   3     <.0001     0.0166                  <.0001     0.6223     0.0293
   4     <.0001     <.0001     <.0001                  <.0001     <.0001
   5     <.0001     0.0731     0.6223     <.0001                  0.0117
   6     <.0001     <.0001     0.0293     <.0001     0.0117
```

NOTE: To ensure overall protection level, only probabilities associated with pre-planned
      comparisons should be used.

Now 2-3, 3-6, and 5-6 are no longer significant.

SAS code and output for one-way ANOVA

If you use SAS to do the adjustment, compare pvalues to $\alpha = 0.05$.

```

Comments on the Bonferroni correction

Remark The Bonferroni correction can be used in any situation. In particular, it can be used on unadjusted pvalues reported in an article that has many tests by comparing their pvalues to α/m where m is the number of tests they perform.

Remark The Bonferroni correction is (in general) the most conservative multiple comparison adjustment we will discuss, i.e. it will lead to the least null hypothesis rejections.

Constructing multiple confidence intervals

Remark A $100(1 - \alpha)\%$ confidence interval should contain the true value $100(1 - \alpha)\%$ of the time.

Remark An error occurs if the confidence interval does not contain the true value.

Just like the Type I error and familywise error rate, we can ask what is the probability at least one confidence interval does not cover the true value.

The procedures we will talk about for confidence intervals have equivalent approaches for hypothesis testing (pvalues). Within these procedures we still have the equivalence between pvalues and CIs.

Constructing multiple confidence intervals

Confidence interval for the difference between group j and group j':

$$\overline{Y}_j - \overline{Y}_{j'} \pm M \, s_p \sqrt{\frac{1}{n_j} + \frac{1}{n_{j'}}}$$

where M is a multiplier that depends on the adjustment procedure:

Procedure	M	Use
LSD	$t_{n-J}(1 - \alpha/2)$	After significant F-test
		(no adjustment)
Dunnett	multivariate t	Compare all groups to control
Tukey-Kramer	$q_{J,n-J}(1 - \alpha)/\sqrt{2}$	All pairwise comparisons
Scheffé	$\sqrt{(J-1)F_{(J-1,n-J)}(1 - \alpha)}$	All contrasts
Bonferroni	$t_{n-J}(1 - \alpha/2m)$	m tests
		(most generic)

False Discovery Rate

Remark Not wanting to make a single mistake is pretty conservative.

In high-throughput fields a more common multiple comparison adjustment is false discovery rate.

Definition
False discovery rate procedures try to control the expected proportion of incorrectly rejected null hypotheses.

How to incorporate multiple comparison adjustments

1. Determine what tests are going to be run (before looking at the data) or what confidence intervals are going to be constructed.
2. Determine which multiple comparison adjustment is the most relevant
3. Use/state that adjustment and interpret your results

Sulfur effect on scab disease in potatoes

The experiment was conducted to investigate the effect of sulfur on controlling scab disease in potatoes. There were seven treatments: control, plus spring and fall application of 300, 600, 1200 lbs/acre of sulfur. The response variable was percentage of the potato surface area covered with scab averaged over 100 random selected potatoes. A completely randomized design was used with 8 replications of the control and 4 replications of the other treatments.

Cochran and Cox. (1957) Experimental Design (2nd ed). pg96 and Agron. J. 80:712-718 (1988)

Scientific question:

- Does sulfur have any impact at all?
- Is there a difference between spring and fall?
- Is there an effect of increased sulfur (expect more sulfur causes less scab)?

**Completely randomized design
potato scab experiment**
Data

Data

Data

Data

Model

Y_{ij}: avg % of surface area covered with scab for plot i in treatment j for $j = 1, \ldots, 7$.

Assume $Y_{ij} \stackrel{ind}{\sim} N(\mu_j, \sigma^2)$.

Hypotheses:

- Difference amongst any means: One-way ANOVA F-test
- *Any effect*: Control vs sulfur
- *Fall vs spring*: Contrast comparing fall vs spring applications
- *Sulfur level*: Linear trend contrast

Control vs sulfur

$$\gamma \quad = \tfrac{1}{6}(\mu_{F12} + \mu_{F6} + \mu_{F3} + \mu_{S3} + \mu_{S6} + \mu_{S12}) - \mu_O$$

$$= \tfrac{1}{6}(\mu_{F12} + \mu_{F6} + \mu_{F3} + \mu_{S3} + \mu_{S6} + \mu_{S12} - 6\mu_O)$$

Fall vs spring contrast

- *Fall vs spring*: Contrast comparing fall vs spring applications

$$\gamma \ = \tfrac{1}{3}(\mu_{F12} + \mu_{F6} + \mu_{F3}) + 0\mu_O - \tfrac{1}{3}(\mu_{S3} + \mu_{S6} + \mu_{S12})$$

$$= \tfrac{1}{3}\mu_{F12} + \tfrac{1}{3}\mu_{F6} + \tfrac{1}{3}\mu_{F3} + 0\mu_O - \tfrac{1}{3}\mu_{S3} - \tfrac{1}{3}\mu_{S6} - \tfrac{1}{3}\mu_{S12}$$

$$= \tfrac{1}{3}\left[\mu_{F12} + \mu_{F6} + \mu_{F3} + 0\mu_O - 1\mu_{S3} - 1\mu_{S6} - 1\mu_{S12}\right]$$

Sulfur level: linear trend contrasts

- The unique sulfur levels (X_i) are 0, 3, 6, and 12.
- So the linear trend contrast ($X_i - \overline{X}$) is

$$
\begin{array}{c|cccc}
X_i & 0 & 3 & 6 & 12 \\
\hline
X_i - \overline{X} & -\frac{21}{4} & -\frac{9}{4} & \frac{3}{4} & \frac{27}{4}
\end{array}
$$

- But 3, 6, and 12 are duplicated, so we need the average of the groups

$$
\begin{aligned}
\gamma \;\; &= -\tfrac{21}{4}\mu_0 - \tfrac{9}{4}\mu_3 + \tfrac{3}{4}\mu_6 + \tfrac{27}{4}\mu_{12} \\[2mm]
&= -\tfrac{21}{4}\mu_0 - \tfrac{9}{4}\left(\tfrac{\mu_{S3}+\mu_{F3}}{2}\right) + \tfrac{3}{4}\left(\tfrac{\mu_{S6}+\mu_{F6}}{2}\right) + \tfrac{27}{4}\left(\tfrac{\mu_{S12}+\mu_{F12}}{2}\right) \\[2mm]
&= \tfrac{1}{8}\left[-42\mu_0 - 9\mu_{S3} - 9\mu_{F3} + 3\mu_{S6} + 3\mu_{F6} + 27\mu_{S12} + 27\mu_{F12}\right]
\end{aligned}
$$

Summary

For this particular data analysis

- Significant differences in means between the groups (ANOVA $F_{6,25} = 3.61$ p=0.01)
- Sulfur had a significant impact on scab (p=0.002)
- Fall was better than spring (p=0.03, 95% CI (0.53, 11.8))
- Linear trend in sulfur was significant(p=0.003)

- Concerned about spatial correlation among columns
- Consider a transformation of the response
  - CI for F12 (-1.2, 12.7)
  - Non-constant variance (residuals vs predicted, sulfur, application)
