STAT 401A - Statistical Methods for Research Workers
Multiple regression models

Jarad Niemi (Dr. J)

Iowa State University

last updated: November 5, 2014

Multiple regression

Recall the simple linear regression model is

$$Y_i \overset{ind}{\sim} N(\beta_0 + \beta_1 X_i, \sigma^2)$$

The multiple regression model is

$$Y_i \overset{ind}{\sim} N(\beta_0 + \beta_1 X_{i,1} + \cdots + \beta_p X_{i,p}, \sigma^2)$$

where

- Y_i is the response for observation i and
- $X_{i,p}$ is the pth explanatory variable for observation i.

We may also write

$$Y_i \overset{ind}{\sim} N(\mu_i, \sigma^2) \quad \text{or} \quad Y_i = \mu_i + e_i, e_i \overset{iid}{\sim} N(0, \sigma^2)$$

where

$$\mu_i = \beta_0 + \beta_1 X_{i,1} + \cdots + \beta_p X_{i,p}.$$

Explanatory variables

There is a lot of flexibility in the mean

$$\mu_i = E[Y_i | X_{i,1}, \ldots, X_{i,p}] = \beta_0 + \beta_1 X_{i,1} + \cdots + \beta_p X_{i,p}$$

as there are many possibilities for the explanatory variables $X_{i,1}, \ldots, X_{i,p}$:

- Higher order terms (X^2)
- Additional explanatory variables $(X_1$ and $X_2)$
- Dummy variables for categorical variables $(X_1 = \mathrm{I}())$
- Interactions $(X_1 X_2)$
  - Continuous-continuous
  - Continuous-categorical
  - Categorical-categorical

Interpretation

Model:
$$Y_i \overset{ind}{\sim} N(\beta_0 + \beta_1 X_{i,1} + \cdots + \beta_p X_{i,p}, \sigma^2)$$

The interpretation is

- β_0 is the expected value of the response Y_i when all explanatory variables are zero.
- β_p, $p \neq 0$ is the expected increase in the response for a one-unit increase in the pth explanatory variable when all other explanatory variables are held constant.
- R^2 is the proportion of the variance in the response explained by the model

Higher order terms (X^2)

Let

- Y_i be the distance for the ith run of the experiment and
- H_i be the height for the ith run of the experiment.

Simple linear regression assumes

$$Y_i \overset{ind}{\sim} N(\beta_0 + \beta_1 H_i \qquad\qquad , \sigma^2)$$
The quadratic multiple regression assumes

$$Y_i \overset{ind}{\sim} N(\beta_0 + \beta_1 H_i + \beta_2 H_i^2 \qquad , \sigma^2)$$

The cubic multiple regression assumes

$$Y_i \overset{ind}{\sim} N(\beta_0 + \beta_1 H_i + \beta_2 H_i^2 + \beta_3 H_i^3, \sigma^2)$$

Case1001

SAS code and output

```
DATA case1001;

Longnose Dace Abundance

From http://udel.edu/~mcdonald/statmultreg.html:

> *I extracted some data from the Maryland Biological Stream Survey. ... The dependent variable is the number of Longnose Dace (Rhinichthys cataractae) per 75-meter section of [a] stream. The independent variables are the area (in acres) drained by the stream; the dissolved oxygen (in mg/liter); the maximum depth (in cm) of the 75-meter segment of stream; nitrate concentration (mg/liter); sulfate concentration (mg/liter); and the water temperature on the sampling date (in degrees C).*
Consider the model

$$Y_i \overset{ind}{\sim} N(\beta_0 + \beta_1 X_{i,1} + \beta_2 X_{i,2}, \sigma^2)$$

where

- Y_i: count of Longnose Dace in stream i
- $X_{i,1}$: maximum depth (in cm) of stream i
- $X_{i,2}$: nitrate concentration (mg/liter) of stream i

Exploratory

```
DATA dace;
  INFILE 'Longnose Dace.csv' DSD FIRSTOBS=2;
  INPUT stream $ count acreage do2 maxdepth no3 so4 temp;

PROC REG DATA=dace;
  MODEL count = maxdepth no3;
  RUN;
```

F-statistic: 7.68 on 2 and 64 DF,  p-value: 0.00102
```

Interpretation

- Intercept (β_0): The expected count of Longnose Dace when maximum depth and nitrate concentration are both zero is -18.
- Coefficient for maxdepth (β_1): Holding nitrate concentration constant, each cm increase in maximum depth is associated with an additional 0.48 Longnose Dace counted on average.
- Coefficient for no3 (β_2): Holding maximum depth constant, each mg/liter increase in nitrate concentration is associated with an addition 8.3 Longnose Dace counted on average.
- Coefficient of determination (R^2): The model explains 19% of the variability in the count of Longnose Dace.

Using a categorical variable as an explanatory variable.
Regression with a categorical variable

- Choose one of the levels as the reference level, e.g. N/N85
- Construct dummy variables using indicator functions for the other levels, e.g.

$$X_{i,1} = \text{I(diet for observation } i \text{ is NP)}$$
$$X_{i,2} = \text{I(diet for observation } i \text{ is N/R50 lopro)}$$
$$X_{i,3} = \text{I(diet for observation } i \text{ is N/R50)}$$
$$X_{i,4} = \text{I(diet for observation } i \text{ is R/R50)}$$
$$X_{i,5} = \text{I(diet for observation } i \text{ is N/R40)}$$

- Run a multiple linear regression using these dummy variables.

An indicator function is

$$\text{I}(A) = \left\{ \begin{array}{ll} 1 & A \text{ is TRUE} \\ 0 & A \text{ is FALSE} \end{array} \right.$$

```

F-statistic: 57.1 on 5 and 343 DF,  p-value: <2e-16
```

Interpretation

- $\beta_0 = E[Y_i|\text{reference level}]$, i.e. expected response for the reference level

  Note: the only way $X_{i,1} = \cdots = X_{i,p} = 0$ is if all indicators are zero, i.e. at the reference level.

- $\beta_p, p > 0$: expected change in the response moving from the reference level to the level associated with the pth dummy variable

  Note: the only way for $X_{i,p}$ to increase by one and all other indicators to stay constant is if initially $X_{i,1} = \cdots = X_{i,p} = 0$ and now $X_{i,p} = 1$

For example,

- The expected lifetime for mice on the N/N85 diet is 37 weeks.
- The expected increase in lifetime for mice on the N/R40 diet compared to the N/N85 diet is 12.4 weeks.
- The model explains 45% of the variability in mice lifetimes.

Using a categorical variable as an explanatory variable.
Interactions

Why an interaction?

> *Two explanatory variables are said to interact if the effect that one of them has on the mean response depends on the value of the other.*

For example,

- Longnose dace: The effect of no3 on longnose dace count depends on the maxdepth. (Continuous-continuous)
- Case1002: The effect of mass on energy depends on the species type. (Continuous-categorical)
- Yield: the effect of fertilizer type depends on the fertilizer brand (Categorical-categorical)

Continuous-continuous interaction

For observation i, let

- Y_i be the response
- $X_{i,1}$ be the first explanatory variable and
- $X_{i,2}$ be the second explanatory variable.

The mean containing only main effects is

$$\mu_i = \beta_0 + \beta_1 X_{i,1} + \beta_2 X_{i,2}.$$

The mean with the interaction is

$$\mu_i = \beta_0 + \beta_1 X_{i,1} + \beta_2 X_{i,2} + \beta_3 X_{i,1} X_{i,2}.$$

Intepretation

- β_0: expected response when explanatory variables are zero
- β_1: expected change in the response for each change in $X_{i,1}$ when $X_{i,2}$ is zero
- β_2: expected change in the response for each change in $X_{i,2}$ when $X_{i,1}$ is zero
- $\beta_3 X_{i,2}$: expected change in the effect of $X_{i,1}$ on the response when $X_{i,2}$ is not zero
- $\beta_3 X_{i,1}$: expected change in the effect of $X_{i,2}$ on the response when $X_{i,1}$ is not zero

For example,

$$
\begin{aligned}
E[Y_i|X_{i,1} = x_1 + 1, X_{i,2} = x_2] &= \beta_0 + \beta_1(x_1+1) + \beta_2 x_2 + \beta_3(x_1+1)x_2 \\
E[Y_i|X_{i,1} = x_1 \quad , X_{i,2} = x_2] &= \beta_0 + \beta_1\, x_1 \quad + \beta_2 x_2 + \beta_3\, x_1 \quad x_2 \\
\hline
&= \quad \beta_1 \quad\quad + \beta_3 \quad\quad x_2
\end{aligned}
$$

R code and output

```
d = read.csv("longnosedace.csv")
m = lm(count ~ maxdepth + no3 + maxdepth:no3, d)
summary(m)

Call:
lm(formula = count ~ maxdepth + no3 + maxdepth:no3, data = d)

Residuals:
   Min    1Q Median    3Q    Max
-65.11 -21.40  -9.56   5.95 151.07

maxdepth     -0.00934    0.32918   -0.03    0.977
no3          -4.64627    7.85693   -0.59    0.556
maxdepth:no3  0.20122    0.11358    1.77    0.081 .
---
Signif. codes:  0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1

Residual standard error: 42.7 on 63 degrees of freedom
Multiple R-squared:  0.232,  Adjusted R-squared:  0.195
F-statistic: 6.34 on 3 and 63 DF,  p-value: 0.000797
```

Continuous-categorical interaction

Let category A be the reference level. Then observation i, let

- Y_i be the response
- $X_{i,1}$ be the continuous explanatory variable,
- B_i be a dummy variable for category B, and
- C_i be a dummy variable for category C.

The mean containing only main effects is

$$\mu_i = \beta_0 + \beta_1 X_{i,1} + \beta_2 B_i + \beta_3 C_i.$$

The mean with the interaction is

$$\mu_i = \beta_0 + \beta_1 X_{i,1} + \beta_2 B_i + \beta_3 C_i + \beta_4 X_{i,1} B_i + \beta_5 X_{i,1} C_i.$$

Interpretation for the main effect model

The mean containing only main effects is

$$\mu_i = \beta_0 + \beta_1 X_{i,1} + \beta_2 B_i + \beta_3 C_i.$$

- β_1 is the change in the response when the continuous explanatory variable increases by one for any category
- when the continuous explanatory variable is zero
  - β_0 is the expected response for category A
  - $\beta_0 + \beta_2$ is the expected response for category B
  - $\beta_0 + \beta_3$ is the expected response for category C

Interpretation for the model with an interaction

The model with an interaction is

$$\mu_i = \beta_0 + \beta_1 X_{i,1} + \beta_2 B_i + \beta_3 C_i + \beta_4 X_{i,1} B_i + \beta_5 X_{i,1} C_i$$

- β_0 is the expected response when the continuous explanatory variable is zero and we are in category A
- β_1 is the change in the response when the continuous explanatory variable increases by one for category A
- When the continuous explanatory variable $(X_{i,1})$ is zero,
  - β_2 is the change in the expected response when moving from category A to category B
  - β_3 is the change in the expected response when moving from category A to category C
- $\beta_1 + \beta_4$ is the change in the response when the continuous explanatory variable increases by one for category B
- $\beta_1 + \beta_5$ is the change in the response when the continuous explanatory variable increases by one for category C

Categorical-categorical

Let category A and type 0 be the reference level. For observation i, let

- Y_i be the response,
- 1_i be a dummy variable for type 1,
- B_i be a dummy variable for category B, and
- C_i be a dummy variable for category C.

The mean containing only main effects is

$$\mu_i = \beta_0 + \beta_1 1_i + \beta_2 B_i + \beta_3 C_i.$$

The mean with an interaction is

$$\mu_i = \beta_0 + \beta_1 1_i + \beta_2 B_i + \beta_3 C_i + \beta_4 1_i B_i + \beta_5 1_i C_i.$$

Interpretation for the main effects model

The mean containing only main effects is

$$\mu_i = \beta_0 + \beta_1 1_i + \beta_2 B_i + \beta_3 C_i.$$

- β_0 is the expected response for category A and type 0
- β_1 is the change in response for moving from type 0 to type 1
- β_2 is the change in response for moving from category A to category B
- β_3 is the change in response for moving from category A to category C

The means are then

| | | Category | |
Type	A	B	C
0	β_0	$\beta_0 + \beta_2$	$\beta_0 + \beta_3$
1	$\beta_0 + \beta_1$	$\beta_0 + \beta_1 + \beta_2$	$\beta_0 + \beta_1 + \beta_3$

Interpretation for the model with an interaction

The mean with an interaction is

$$\mu_i = \beta_0 + \beta_1 1_i + \beta_2 B_i + \beta_3 C_i + \beta_4 1_i B_i + \beta_5 1_i C_i.$$

- β_0 is the expected response for category A and type 0
- β_1 is the change in response for moving from type 0 to type 1 for category A
- β_2 is the change in response for moving from category A to category B for type 0
- β_3 is the change in response for moving from category A to category C for type 0
- β_4 is the difference in change in response for moving from category A to category B for type 1 compared to type 0
- β_5 is the difference in change in response for moving from category A to category C for type 1 compared to type 0

The means are then

| | Category | | |
Type	A	B	C
0	β_0	$\beta_0 + \beta_2$	$\beta_0 + \beta_3$
1	$\beta_0 + \beta_1$	$\beta_0 + \beta_1 + \beta_2 + \beta_4$	$\beta_0 + \beta_1 + \beta_3 + \beta_5$

This is referred to as the cell-means model.

When to include interaction terms

From _The Statistical Sleuth (3rd ed)_ page 250:

- when a question of interest pertains to an interaction
- when good reason exists to suspect interaction or
- when interactions are proposed as a more general model for the purpose of examining the goodness of fit of a model without interaction

Multiple regression explanatory variables

The possibilities for explanatory variables are

- Higher order terms (X^2)
- Additional explanatory variables (X_1 and X_2)
- Dummy variables for categorical variables ($X_1 = \mathrm{I}()$)
- Interactions ($X_1 X_2$)
  - Continuous-continuous
  - Continuous-categorical
  - Categorical-categorical

We can also combine these explanatory variables, e.g.

- including higher order terms for continuous variables along with dummy variables for categorical variables and
- including higher order interactions ($X_1 X_2 X_3$).
